This is a compilation of solutions for the 2015 JMO. Some of the solutions are my own work, but many are from the official solutions provided by the organizers (for which they hold any copyrights), and others were found on the Art of Problem Solving forums.

Corrections and comments are welcome!
§0 Problems

1. Given a sequence of real numbers, a move consists of choosing two terms and replacing each with their arithmetic mean. Show that there exists a sequence of 2015 distinct real numbers such that after one initial move is applied to the sequence — no matter what move — there is always a way to continue with a finite sequence of moves so as to obtain in the end a constant sequence.

2. Solve in integers the equation
   \[ x^2 + xy + y^2 = \left( \frac{x + y}{3} + 1 \right)^3. \]

3. Quadrilateral $APBQ$ is inscribed in circle $\omega$ with $\angle P = \angle Q = 90^\circ$ and $AP = AQ < BP$. Let $X$ be a variable point on segment $PQ$. Line $AX$ meets $\omega$ again at $S$ (other than $A$). Point $T$ lies on arc $AQB$ of $\omega$ such that $\overline{XT}$ is perpendicular to $\overline{AX}$. Let $M$ denote the midpoint of chord $ST$.

   As $X$ varies on segment $PQ$, show that $M$ moves along a circle.

4. Find all functions $f : \mathbb{Q} \to \mathbb{Q}$ such that
   \[ f(x) + f(t) = f(y) + f(z) \]
   for all rational numbers $x < y < z < t$ that form an arithmetic progression.

5. Let $ABCD$ be a cyclic quadrilateral. Prove that there exists a point $X$ on segment $BD$ such that $\angle BAC = \angle XAD$ and $\angle BCA = \angle XCD$ if and only if there exists a point $Y$ on segment $AC$ such that $\angle CBD = \angle YBA$ and $\angle CDB = \angle YDA$.

6. Steve is piling $m \geq 1$ indistinguishable stones on the squares of an $n \times n$ grid.

   Each square can have an arbitrarily high pile of stones. After he finished piling his stones in some manner, he can then perform stone moves, defined as follows.

   Consider any four grid squares, which are corners of a rectangle, i.e. in positions $(i, k), (i, l), (j, k), (j, l)$ for some $1 \leq i, j, k, l \leq n$, such that $i < j$ and $k < l$. A stone move consists of either removing one stone from each of $(i, k)$ and $(j, l)$ and moving them to $(i, l)$ and $(j, k)$ respectively, or removing one stone from each of $(i, l)$ and $(j, k)$ and moving them to $(i, k)$ and $(j, l)$ respectively.

   Two ways of piling the stones are equivalent if they can be obtained from one another by a sequence of stone moves. How many different non-equivalent ways can Steve pile the stones on the grid?
§1 JMO 2015/1, proposed by Milan Haiman

Given a sequence of real numbers, a move consists of choosing two terms and replacing each with their arithmetic mean. Show that there exists a sequence of 2015 distinct real numbers such that after one initial move is applied to the sequence — no matter what move — there is always a way to continue with a finite sequence of moves so as to obtain in the end a constant sequence.

One valid example of a sequence is 0, 1, \ldots, 2014. We will show how to achieve the all-1007 sequence based on the first move.

Say two numbers are 

opposites

if their average is 1007. We consider 1007 as its own opposite.

We consider two cases:

- First, suppose the first initial move did not involve the number 1007. Suppose the two numbers changed were \(a\) and \(b\), replaced by \(c = \frac{1}{2}(a + b)\) twice.
  - If \(a\) and \(b\) are opposites, we simply operate on all the other pairs of opposites.
  - Otherwise let \(a'\) and \(b'\) be the opposites of \(a\) and \(b\), so all four of \(a, b, a', b'\) are distinct. Then operate on \(a'\) and \(b'\) to get \(c' = 2014 - c\). We work with only these four numbers and replace them as follows:

\[
\begin{array}{cccc}
\frac{1}{2}(a + b) & \frac{1}{2}(a + b) & a' & b' \\
\frac{1}{2}(a + b) & \frac{1}{2}(a + b) & \frac{1}{2}(a' + b') & \frac{1}{2}(a' + b') \\
1007 & 1007 & 1007 & 1007 \\
1007 & 1007 & 1007 & 1007 \\
\end{array}
\]

Finally, we operate on the remaining 1005 pairs of opposites.

- Now suppose the first initial move involved the number 1007 and some \(a\). Let \(k\) be any number other than \(a\) or its opposite, and let \(a', k'\) be the opposites of \(a\) and \(k\).

We work with only these five numbers: and replace them in the following way:

\[
\begin{array}{cccc}
\frac{1}{2}(a + 1007) & \frac{1}{2}(a + 1007) & a' & k \\
\frac{1}{2}(a + 1007) & \frac{1}{2}(a + 1007) & a' & 1007 \\
\frac{1}{2}(a + 1007) & \frac{1}{2}(a + 1007) & a' & 1007 \\
\frac{1}{2}(a + 1007) & \frac{1}{2}(a + 1007) & a' & 1007 \\
1007 & 1007 & 1007 & 1007 \\
1007 & 1007 & 1007 & 1007 \\
\end{array}
\]

Finally, we operate on the remaining 1005 pairs of opposites.

Remark. In fact, the same proof basically works for any sequence with average \(m\) such that \(m\) is in the sequence, and every term has an opposite.

However for “most” sequences one expects the result to not be possible. As a simple example, the goal is impossible for \((0, 1, \ldots, 2013, 2015)\) since the average of the terms is \(1007 + \frac{1}{2015}\), but in the process the only denominators ever generated are powers of 2. This narrows the search somewhat.
\section*{§2 JMO 2015/2, proposed by Titu Andreescu}

Solve in integers the equation
\[ x^2 + xy + y^2 = \left( \frac{x + y}{3} + 1 \right)^3. \]

We do the trick of setting \( a = x + y \) and \( b = x - y \). This rewrites the equation as
\[ \frac{1}{4} ((a + b)^2 + (a + b)(a - b) + (a - b)^2) = \left( \frac{a}{3} + 1 \right)^3 \]
where \( a, b \in \mathbb{Z} \) have the same parity. This becomes
\[ 3a^2 + b^2 = 4 \left( \frac{a}{3} + 1 \right)^3 \]
which is enough to imply \( 3 \mid a \), so let \( a = 3c \). Miraculously, this becomes
\[ b^2 = (c - 2)^2(4c + 1). \]

So a solution must have \( 4c + 1 = m^2 \), with \( m \) odd. This gives
\[ x = \frac{1}{8} \left( 3(m^2 - 1) \pm (m^3 - 9m) \right) \quad \text{and} \quad y = \frac{1}{8} \left( 3(m^2 - 1) \mp (m^3 - 9m) \right). \]

For mod 8 reasons, this always generates a valid integer solution, so this is the complete curve of solutions. Actually, putting \( m = 2n + 1 \) gives the much nicer curve
\[ x = n^3 + 3n^2 - 1 \quad \text{and} \quad y = -n^3 + 3n + 1 \]
and permutations.

For \( n = 0, 1, 2, 3 \) this gives the first few solutions are \((-1, 1), (3, 3), (19, -1), (53, -17)\), (and permutations).
§3 JMO 2015/3, proposed by Zuming Feng

Quadrilateral $APBQ$ is inscribed in circle $\omega$ with $\angle P = \angle Q = 90^\circ$ and $AP = AQ < BP$. Let $X$ be a variable point on segment $PQ$. Line $AX$ meets $\omega$ again at $S$ (other than $A$). Point $T$ lies on arc $AQB$ of $\omega$ such that $XT$ is perpendicular to $AX$. Let $M$ denote the midpoint of chord $ST$.

As $X$ varies on segment $PQ$, show that $M$ moves along a circle.

We present three solutions, one by complex numbers, two more synthetic. (A fourth solution using median formulas is also possible.) Most solutions will prove that the center of the fixed circle is the midpoint of $AO$ (with $O$ the center of $\omega$); this can be recovered empirically by letting

- $X$ approach $P$ (giving the midpoint of $BP$)
- $X$ approach $Q$ (giving the point $Q$), and
- $X$ at the midpoint of $PQ$ (giving the midpoint of $BQ$)

which determines the circle; this circle then passes through $P$ by symmetry and we can find the center by taking the intersection of two perpendicular bisectors (which two?).

**Complex solution (Evan Chen)** Toss on the complex unit circle with $a = -1$, $b = 1$, $z = -\frac{1}{2}$. Let $s$ and $t$ be on the unit circle. We claim $Z$ is the center.

It follows from standard formulas that

$$x = \frac{1}{2} (s + t - 1 + s/t)$$

thus

$$4 \text{Re} x + 2 = s + t + \frac{1}{s} + \frac{1}{t} + \frac{s}{t} + \frac{t}{s}$$

which depends only on $P$ and $Q$, and not on $X$. Thus

$$4 \left| z - \frac{s + t}{2} \right|^2 = |s + t + 1|^2 = 3 + (4 \text{Re} x + 2)$$

does not depend on $X$, done.

**Homothety solution (Alex Whatley)** Let $G$, $N$, $O$ denote the centroid, nine-point center, and circumcenter of triangle $AST$, respectively. Let $Y$ denote the midpoint of $AS$. Then the three points $X$, $Y$, $M$ lie on the nine-point circle of triangle $AST$, which is centered at $N$ and has radius $\frac{1}{2} AO$. 

5
Let $R$ denote the radius of $\omega$. Note that the nine-point circle of $\triangle AST$ has radius equal to $\frac{1}{2}R$, and hence is independent of $S$ and $T$. Then the power of $A$ with respect to the nine-point circle equals

$$AN^2 - \left(\frac{1}{2}R\right)^2 = AX \cdot AY = \frac{1}{2}AX \cdot AS = \frac{1}{2}AQ^2$$

and hence

$$AN^2 = \left(\frac{1}{2}R\right)^2 + \frac{1}{2}AQ^2$$

which does not depend on the choice of $X$. So $N$ moves along a circle centered at $A$.

Since the points $O$, $G$, $N$ are collinear on the Euler line of $\triangle AST$ with

$$GO = \frac{2}{3}NO$$

it follows by homothety that $G$ moves along a circle as well, whose center is situated one-third of the way from $A$ to $O$. Finally, since $A$, $G$, $M$ are collinear with

$$AM = \frac{3}{2}AG$$

it follows that $M$ moves along a circle centered at the midpoint of $AO$.

**Power of a point solution (Zuming Feng, official solution)** We complete the picture by letting $\triangle KYX$ be the orthic triangle of $\triangle AST$; in that case line $XY$ meets the $\omega$ again at $P$ and $Q$. 
The main claim is:

**Claim** — Quadrilateral $PQKM$ is cyclic.

*Proof.* To see this, we use power of a point: let $V = QXYP \cap SKMT$. One approach is that since $(VK;ST) = -1$ we have $VQ \cdot VP = VS \cdot VT = VK \cdot VM$. A longer approach is more elementary:

$$VQ \cdot VP = VS \cdot VT = VX \cdot VY = VK \cdot VM$$

using the nine-point circle, and the circle with diameter $ST$. \qed

But the circumcenter of $PQKM$, is the midpoint of $AO$, since it lies on the perpendicular bisectors of $KM$ and $PQ$. So it is fixed, the end.
§4 JMO 2015/4

Find all functions \( f : \mathbb{Q} \to \mathbb{Q} \) such that

\[
f(x) + f(t) = f(y) + f(z)
\]

for all rational numbers \( x < y < z < t \) that form an arithmetic progression.

Answer: any linear function \( f \). These work.

Here is one approach: for any \( a \) and \( d > 0 \)

\[
f(a) + f(a + 3d) = f(a + d) + f(a + 2d) \\
f(a - d) + f(a + 2d) = f(a) + f(a + d)
\]

which imply

\[
f(a - d) + f(a + 3d) = 2f(a + d).
\]

Thus we conclude that for arbitrary \( x \) and \( y \) we have

\[
f(x) + f(y) = 2f\left(\frac{x + y}{2}\right)
\]

thus \( f \) satisfies Jensen functional equation over \( \mathbb{Q} \), so linear.

The solution can be made to avoid appealing to Jensen’s functional equation; here is a presentation of such a solution based on the official ones. Let \( d > 0 \) be a positive integer, and let \( n \) be an integer. Consider the two equations

\[
f\left(\frac{2n - 1}{2d}\right) + f\left(\frac{2n + 2}{2d}\right) = f\left(\frac{2n}{2d}\right) + f\left(\frac{2n + 1}{2d}\right) \\
f\left(\frac{2n - 2}{2d}\right) + f\left(\frac{2n + 1}{2d}\right) = f\left(\frac{2n - 1}{2d}\right) + f\left(\frac{2n}{2d}\right)
\]

Summing them and simplifying implies that

\[
f\left(\frac{n - 1}{d}\right) + f\left(\frac{n + 1}{d}\right) = 2f\left(\frac{n}{d}\right)
\]

or equivalently \( f\left(\frac{n}{d}\right) - f\left(\frac{n-1}{d}\right) = f\left(\frac{n+1}{d}\right) - f\left(\frac{n}{d}\right) \). This implies that on the set of rational numbers with denominator dividing \( d \), the function \( f \) is linear.

In particular, we should have \( f\left(\frac{n}{d}\right) = f(0) + \frac{n}{d}f(1) \) since \( \frac{n}{d}, 0, 1 \) have denominators dividing \( d \). This is the same as saying \( f(q) = f(0) + qf(1) \) for any \( q \in \mathbb{Q} \), which is what we wanted to prove.
§5 JMO 2015/5

Let $ABCD$ be a cyclic quadrilateral. Prove that there exists a point $X$ on segment $BD$ such that $\angle BAC = \angle XAD$ and $\angle BCA = \angle XCD$ if and only if there exists a point $Y$ on segment $AC$ such that $\angle CBD = \angle YBA$ and $\angle CDB = \angle YDA$.

Both conditions are equivalent to $ABCD$ being harmonic.

Here is a complex solution. Extend $U$ and $V$ and shown. Thus $u = bd/a$ and $v = bd/c$.

Note $AV \cap CU$ lies on the perpendicular bisector of $BD$ unconditionally. Then $X$ exists as described if and only if the midpoint of $BD$ lies on $AV$. In complex numbers this is $a + v = m + am$, or

$$a + \frac{bd}{c} = b + d + \frac{abd}{c} \cdot \frac{b + d}{2bd} \iff 2(ac + bd) = (b + d)(a + c)$$

which is symmetric.
§6 JMO 2015/6

Steve is piling \( m \geq 1 \) indistinguishable stones on the squares of an \( n \times n \) grid. Each square can have an arbitrarily high pile of stones. After he finished piling his stones in some manner, he can then perform stone moves, defined as follows. Consider any four grid squares, which are corners of a rectangle, i.e. in positions \((i, k), (i, l), (j, k), (j, l)\) for some \(1 \leq i, j, k, l \leq n\), such that \(i < j\) and \(k < l\). A stone move consists of either removing one stone from each of \((i, k)\) and \((j, l)\) and moving them to \((i, l)\) and \((j, k)\) respectively, or removing one stone from each of \((i, l)\) and \((j, k)\) and moving them to \((i, k)\) and \((j, l)\) respectively.

Two ways of piling the stones are equivalent if they can be obtained from one another by a sequence of stone moves. How many different non-equivalent ways can Steve pile the stones on the grid?

The answer is \( \binom{m+n-1}{n-1}^2 \). The main observation is that the multi-set of column counts, and the multi-set of row counts, remains invariant. We call the pair \((X, Y)\) of multisets the signature of the configuration.

We are far from done. This problem is a good test of mathematical maturity since the following steps are then necessary:

1. Check that signatures are invariant around moves (trivial)
2. Check conversely that two configurations are equivalent if they have the same signatures (the hard part of the problem), and
3. Show that each signature is realized by at least one configuration (not immediate, but pretty easy).

Most procedures to the second step are algorithmic in nature, but Ankan Bhattacharya gives the following far cleaner approach. Rather than having a grid of stones, we simply consider the multiset of ordered pairs \((x, y)\). Then, the signatures correspond to the multisets of \(x\) and \(y\) coordinates, while a stone move corresponds to switching two \(y\)-coordinates in different pairs, say.

Then, the second part is completed just because transpositions generate any permutation. To be explicit, given two sets of stones, we can permute the labels so that the first set is \((x_1, y_1), \ldots, (x_m, y_m)\) and the second set of stones is \((x_1', y_1'), \ldots, (x_m', y_m')\). Then we just induce the correct permutation on \((y_i)\) to get \((y_i')\).

The third part is obvious since given two multisets \(X = \{x_1, \ldots, x_m\}\) and \(Y = \{y_1, \ldots, y_m\}\) we just put stones at \((x_i, y_i)\) for \(i = 1, \ldots, m\).

In that sense, the entire grid is a huge red herring!
