TWITCH SOLVES ISL

Episode 12

Problem

A set A of integers is called *sum-full* if $A \subseteq A + A$. A set A of integers is said to be *zero-sum-free* if 0 is the only integer that cannot be expressed as the sum of the elements of a finite nonempty subset of A . Does there exist a sum-full zero-sum-free set of integers?

Solution

The answer is YES, such a set exists, and is given by

$$A = \{1, -2, 3, -5, 8, -13, 21, -34, 55, \dots\}.$$

To prove every number can be expressed as a (possibly empty) subset of A , we have the following stronger claim.

Claim. Let N be an integer (possibly zero or negative). Let F denote the smallest Fibonacci number which is strictly greater than $|N|$. Then there exists a representation of N as the sum of a (possibly empty) subset of A , where no element used has absolute value greater than N .

Proof. By induction on $|N|$. Omitted. □

On the other hand, the *Zeckendorf representation theorem* implies that it's not possible to express 0 as a nonempty subset; such a representation would amount to an identity of the form

$$F_{i_1} + F_{i_2} + \dots = F_{j_1} + F_{j_2} + \dots$$

where no terms on either side are consecutive, and both sides have no common terms; and this is impossible.
