## Problem

Let $\omega$ be the incircle of a fixed equilateral triangle $A B C$. Let $\ell$ be a variable line that is tangent to $\omega$ and meets the interior of segments $B C$ and $C A$ at points $P$ and $Q$, respectively. A point $R$ is chosen such that $P R=P A$ and $Q R=Q B$. Find all possible locations of the point $R$, over all choices of $\ell$.

## Solution

Let $r$ be the inradius. Let $T$ be the tangency point of $\overline{P Q}$ on arc $\widehat{D E}$ of the incircle, which we consider varying. We define $R_{1}$ and $R_{2}$ to be the two intersections of the circle centered at $P$ with radius $P A$, and the circle centered at $Q$ with radius $Q B$. We choose $R_{1}$ to lie on the opposite side of $C$ as line $P Q$.

Claim. The point $R_{1}$ is the unique point on ray $T I$ with $R_{1} I=2 r$.
Proof. Define $S$ to be the point on ray $T I$ with $S I=2 r$. Note that there is a homothety at $I$ which maps $\triangle D T E$ to $\triangle A S B$, for some point $S$.

Note that since TASD is an isosceles trapezoid, it follows $P A=P S$. Similarly, $Q B=Q S$. So it follows that $S=R_{1}$.

Since $T$ can be any point on the open arc $\widehat{D E}$, it follows that the locus of $R_{1}$ is exactly the open $120^{\circ}$ arc of $\widehat{A B}$ of the circle centered at $I$ with radius $2 r$ (i.e. the circumcircle of $A B C$ ).

It remains to characterize $R_{2}$. Since $T I=r, I R_{1}=2 r$, it follows $T R_{2}=3 r$ and $I R_{2}=4 r$. Define $A^{\prime}$ on ray $D I$ such that $A^{\prime} I=4 r$, and $B^{\prime}$ on ray $I E$ such that $B^{\prime} I=4 r$. Then it follows, again by homothety, that the locus of $R_{2}$ is the $120^{\circ}$ arc $\widehat{A^{\prime} B^{\prime}}$ of the circle centered at $I$ with radius $4 r$.
In conclusion, the locus of $R$ is the two open $120^{\circ}$ arcs we identified.
