TWITCH SOLVES ISL

Episode 48

Problem

Let $\triangle ABC$ be an acute triangle with circumcenter O , and let $Q \neq A$ denote the point on $\odot(ABC)$ for which $AQ \perp BC$. The circumcircle of $\triangle BOC$ intersects lines AC and AB for the second time at D and E respectively. Suppose that AQ , BC , and DE are concurrent. If $OD = 3$ and $OE = 7$, compute AQ .

Solution

Let L be the concurrency point, so by radical axis $AEQD$ is cyclic.

Claim. Line DLE is the Simson line from Q to ABC .

Proof. Note

$$\angle BED = \angle BCD = \angle BCA = \angle BQA = \angle BQL$$

so $BEQL$ is cyclic, hence $\angle QEB = \angle QLB = 90^\circ$, as desired. □

Claim. $OEQD$ is a parallelogram.

Proof. Since $\angle OED = \angle OCD = 90^\circ - A$, we find $\overline{OE} \perp \overline{AC}$. But $\overline{QD} \perp \overline{AC}$ too. □

The parallelogram law now gives

$$DE^2 + OQ^2 = 2(OD^2 + OE^2).$$

Also since O is the orthocenter of $\triangle ADE$ it is known that

$$AO^2 = AQ^2 - DE^2.$$

Putting these two together and noting $AO = OQ$ gives $AQ^2 = 2(OD^2 + OE^2) = 116$, hence $AQ = 2\sqrt{29}$.
